Understanding Like Terms in Algebra

Like terms are algebraic expressions that contain the same variables raised to the same powers, although their coefficients may differ. Recognizing and combining like terms is a foundational skill in algebra that simplifies expressions and equations, making them easier to solve. For example, the terms $3x$ and $5x$ are like terms because both contain the variable x to the first power. In contrast, $3x$ and $3x^2$ are not like terms, as the exponents differ.

Definition and Characteristics of Like Terms

Like terms must have identical variable parts, including both the variable's base and its exponent. The coefficients, or numerical multipliers, can be different and are the values combined during the simplification process. Understanding this concept is critical for correctly performing operations such as addition and subtraction on algebraic expressions.

Examples of Like and Unlike Terms

To clarify, consider the following examples:

- Like terms: $7y$ and $-2y$, $4ab$ and $9ab$
- Not like terms: $5x$ and $5y$, $3x^2$ and $3x$

Being able to distinguish between like and unlike terms is the first step in mastering algebraic simplification and is a focus of math worksheets combining like terms.
