**proof by mathematical induction examples** serve as essential tools in understanding and applying one of the most fundamental methods of mathematical proof. This technique is widely used to establish the truth of an infinite sequence of statements, typically indexed by natural numbers. Mastering proof by mathematical induction is crucial for students and professionals dealing with discrete mathematics, computer science, and various branches of theoretical mathematics. This article delves into several comprehensive proof by mathematical induction examples, illustrating the step-by-step process to demonstrate the validity of propositions. It will also discuss the principle behind induction, common pitfalls, and tips for constructing sound inductive proofs. By exploring diverse examples, readers can gain a deeper grasp of how to leverage this powerful proof method effectively.

## The Principle of Mathematical Induction

The principle of mathematical induction is a fundamental proof technique used to verify that a statement  $P(n)$  holds true for all natural numbers  $n$  greater than or equal to a certain base case. It involves two main steps: the base case and the inductive step. First, the base case verifies that the statement is true for the initial value, usually  $n = 1$  or  $n = 0$ . Next, the inductive step assumes that the statement holds for some arbitrary natural number  $k$  (the induction hypothesis) and then proves that it must also be true for  $k + 1$ . Successfully completing these steps ensures the statement's validity for all natural numbers beyond the base case. This logical approach is often likened to a domino effect, where pushing the first domino (base case) causes all subsequent dominoes (statements for all  $n$ ) to fall.

## Simple Proof by Mathematical Induction Example

To illustrate proof by mathematical induction examples, consider the proposition that the sum of the first  $n$  odd numbers equals  $n$  squared. Formally, this can be expressed as:

$$1 + 3 + 5 + \dots + (2n - 1) = n^2$$

This example demonstrates the basic structure of an inductive proof clearly and effectively.

## Base Case

For  $n = 1$ , the left side is 1, and the right side is  $1^2 = 1$ . Both sides are equal, so the base case holds.

## Inductive Step

Assume the statement holds for some arbitrary natural number  $k$ , meaning:

$$1 + 3 + 5 + \dots + (2k - 1) = k^2$$

Now, consider  $n = k + 1$ :

$$1 + 3 + 5 + \dots + (2k - 1) + (2(k + 1) - 1) = k^2 + (2k + 1) = (k + 1)^2$$

This confirms the statement is true for  $k + 1$ , completing the inductive step.

## Sum of the First $n$ Natural Numbers

Another classical example in proof by mathematical induction examples is the formula for the sum of the first  $n$  natural numbers:

$$1 + 2 + 3 + \dots + n = n(n + 1)/2$$

This proposition can be verified using induction to solidify understanding of the method and its practical applications.

## Base Case

When  $n = 1$ , the sum is 1, and the right side equals  $1(1 + 1)/2 = 1$ , so the base case is true.

## Inductive Step

Assume for  $n = k$ , the sum holds:

$$1 + 2 + 3 + \dots + k = k(k + 1)/2$$

For  $n = k + 1$ , add  $(k + 1)$  to both sides:

$$1 + 2 + 3 + \dots + k + (k + 1) = k(k + 1)/2 + (k + 1)$$

Factoring  $(k + 1)$  yields:

$$k(k + 1)/2 + (k + 1) = (k + 1)(k/2 + 1) = (k + 1)(k + 2)/2$$

This matches the formula with  $n$  replaced by  $k + 1$ , confirming the inductive step.

# Proof of Inequalities Using Induction

Proof by mathematical induction examples are not limited to equalities; they also extend to inequalities. Inductive proofs are often utilized to confirm that certain inequalities hold for all natural numbers, such as demonstrating growth behavior or bounding functions.

## Example: Proving $2^n \geq n + 1$ for $n \geq 0$

This inequality claims that powers of 2 grow at least as fast as a linear function of  $n$  plus one.

### Base Case

For  $n = 0$ ,  $2^0 = 1$  and  $n + 1 = 1$ , so the inequality holds with equality.

### Inductive Step

Assume  $2^k \geq k + 1$  for some  $k \geq 0$ . Then for  $n = k + 1$ :

$$2^{k+1} = 2 \cdot 2^k \geq 2(k + 1) = 2k + 2$$

Since  $k + 2 \leq 2k + 2$  for  $k \geq 0$ , it follows that:

$$2^{k+1} \geq k + 2 = (k + 1) + 1$$

Therefore,  $2^n \geq n + 1$  holds for  $n = k + 1$ , completing the proof.

## Induction in Divisibility Problems

Divisibility statements provide another rich area for proof by mathematical induction examples. Inductive reasoning can confirm that certain expressions are divisible by a fixed integer for all natural numbers.

## Example: Prove $7^n - 1$ is divisible by 6 for all $n \geq 1$

This problem verifies that the expression  $7^n - 1$  produces multiples of 6 for all positive integers  $n$ .

### Base Case

For  $n = 1$ ,  $7^1 - 1 = 6$ , which is divisible by 6.

## Inductive Step

Assume  $7^k - 1$  is divisible by 6, meaning there exists an integer  $m$  such that  $7^k - 1 = 6m$ .

Consider  $n = k + 1$ :

$$7^{k+1} - 1 = 7 \cdot 7^k - 1 = 7(7^k - 1) + 7 - 1$$

By the induction hypothesis,  $7^k - 1 = 6m$ , so:

$$7^{k+1} - 1 = 7 \cdot 6m + 6 = 6(7m + 1)$$

This expression is divisible by 6, confirming the inductive step.

## Strong Induction and Its Examples

Strong induction, a variation of the standard induction method, assumes the statement holds for all natural numbers less than or equal to  $k$  to prove it for  $k + 1$ . This approach is particularly useful when the truth of  $P(k + 1)$  depends on multiple previous cases rather than just  $P(k)$ .

### Example: Proving Every Natural Number Greater Than 1 is a Product of Primes

This fundamental theorem in number theory can be established using strong induction.

#### Base Case

For  $n = 2$ , the number is prime itself, so it is trivially a product of primes.

#### Inductive Step

Assume every number from 2 up to  $k$  can be factored into primes. For  $n = k + 1$ :

- If  $k + 1$  is prime, it is already a product of primes (itself).
- If  $k + 1$  is composite, it can be expressed as a product of two natural numbers  $a$  and  $b$ , both less than or equal to  $k$ .

By the induction hypothesis, both  $a$  and  $b$  can be factored into primes. Multiplying these prime factorizations gives the prime factorization of  $k + 1$ .

This completes the strong induction proof.

## Frequently Asked Questions

### What is a simple example of proof by mathematical induction?

A classic example is proving that the sum of the first  $n$  natural numbers is  $(n(n+1))/2$ . The base case for  $n=1$  holds since  $1 = (1*2)/2$ . Assuming true for  $n=k$ , we prove for  $n=k+1$  by adding  $(k+1)$  to both sides.

### How do you prove that the sum of the first $n$ odd numbers is $n^2$ using induction?

Base case: For  $n=1$ , sum is 1 which equals  $1^2$ . Assume true for  $n=k$ , meaning sum of first  $k$  odd numbers is  $k^2$ . For  $n=k+1$ , add the next odd number  $(2k+1)$  to  $k^2$ , resulting in  $k^2 + 2k + 1 = (k+1)^2$ , proving the statement.

### Can mathematical induction be used to prove inequalities? Give an example.

Yes, induction can prove inequalities. For example, prove that  $2^n \geq n+1$  for all  $n \geq 1$ . Base case:  $2^1 = 2 \geq 2$ . Assume true for  $n=k$ , so  $2^k \geq k+1$ . For  $n=k+1$ ,  $2^{k+1} = 2*2^k \geq 2(k+1) \geq (k+1)+1$ , completing the induction.

### What is strong induction and how does it differ from simple induction?

Strong induction assumes the statement is true for all values up to  $n=k$  to prove it for  $n=k+1$ , rather than assuming it for just  $n=k$ . This is useful when the proof for  $n=k+1$  depends on multiple previous cases.

### How to prove the formula for the sum of a geometric series using induction?

To prove  $S_n = a(1 - r^n)/(1 - r)$  for  $r \neq 1$ , base case  $n=1$  holds as  $S_1 = a$ . Assume true for  $n=k$ , then for  $n=k+1$ ,  $S_{k+1} = S_k + ar^k$ . Substitute the assumption and simplify to get the formula for  $n=k+1$ .

### Can you provide an example of induction proof involving divisibility?

Prove that 7 divides  $8^n - 1$  for all  $n \geq 1$ . Base case  $n=1$ :  $8^1 - 1 = 7$ , divisible by 7. Assume true for  $n=k$ , so 7 divides  $8^k - 1$ . Then for  $n=k+1$ ,  $8^{k+1} - 1 = 8*8^k - 1 = 8(8^k - 1) + 7$ . This is divisible by 7, completing the induction.

# What are common mistakes to avoid in proofs by induction?

Common mistakes include not verifying the base case properly, assuming the statement for  $n=k+1$  without justification, and failing to correctly apply the induction hypothesis. It's important to clearly state both the base case and the inductive step.
