Basic R Functions

Basic R functions form the foundation of data analysis and programming in R. These functions handle fundamental operations such as creating vectors, sequences, and managing data structures. Mastery of these functions is crucial for efficient coding and manipulation of data in R.

Vector and Sequence Functions

Vectors are the most basic data structures in R, and several functions facilitate their creation and manipulation. The `c()` function combines values into a vector, while `seq()` generates sequences of numbers with specified increments.

- **c(...)**: Combines values into a vector.
- **seq(from, to, by)**: Creates a numeric sequence.
- **rep(x, times)**: Repeats elements of a vector.

- **length(x)**: Returns the length of a vector.

Data Structure Functions

Understanding data structures is critical, and these functions help inspect and manipulate different types of objects in R.

- **class(x)**: Returns the class/type of an object.
- **str(x)**: Displays the structure of an object.
- **typeof(x)**: Identifies the internal type of an object.
- **dim(x)**: Returns dimensions of an object, useful for matrices and data frames.
- **names(x)**: Retrieves or sets the names of elements in a vector or list.

Data Manipulation Functions

Data manipulation functions enable users to clean, transform, and summarize datasets efficiently. These functions are essential for preparing data for analysis and extracting meaningful insights.

Subsetting and Indexing

Extracting subsets of data is common during analysis. R provides flexible methods to subset vectors, lists, and data frames using brackets and functions.

- **[]**: Extract elements by position or condition.
- **subset()**: Returns subsets of data frames based on conditions.
- **which()**: Identifies indices where conditions are TRUE.
- **match()**: Finds positions of matches between vectors.

Data Frame Manipulation

Data frames are central to data analysis in R. These functions help modify, add, or remove data frame components.

- **head(x, n)**: Returns the first *n* rows of a data frame.

- **tail(x, n)**: Returns the last n rows.
- **merge(x, y)**: Combines data frames by common columns.
- **transform()**: Adds new columns or modifies existing ones.
- **aggregate()**: Summarizes data by groups.

Apply Family of Functions

The apply family functions provide powerful tools to perform operations over collections of data without explicit loops, enhancing performance and code readability.

- **apply(X, MARGIN, FUN)**: Applies a function over margins of matrices or arrays.
- **lapply(X, FUN)**: Applies a function to each element of a list and returns a list.
- **sapply(X, FUN)**: Similar to *lapply* but attempts to simplify the output.
- **tapply(X, INDEX, FUN)**: Applies a function over subsets of a vector.

Statistical Functions

Statistical functions in R cover a wide range of analyses, from descriptive statistics to hypothesis testing. These functions are integral to performing rigorous data analysis and interpretation.

Descriptive Statistics

Basic statistical summaries provide quick insights into the distribution and central tendencies of data.

- **mean(x)**: Calculates the average of numeric data.
- **median(x)**: Finds the median value.
- **sd(x)**: Computes the standard deviation.
- **var(x)**: Calculates variance.
- **summary(x)**: Provides a five-number summary plus mean.

Probability Distributions and Tests

R supports a wide array of probability distributions and statistical tests that facilitate hypothesis testing and inferential statistics.

- **dnorm(x, mean, sd)**: Density function for normal distribution.
- **pnorm(q, mean, sd)**: Cumulative distribution function.
- **rnorm(n, mean, sd)**: Generates random normal variables.
- **t.test(x, y)**: Performs t-tests to compare means.
- **cor(x, y)**: Calculates correlation coefficients.

Data Visualization Functions

Visualization is a key component of data analysis, and R offers robust functions to create insightful charts and graphs. These functions facilitate the communication of data trends and patterns effectively.

Base Plotting Functions

R's base graphics system includes simple yet versatile functions for creating a variety of plots.

- **plot(x, y)**: Creates scatterplots or line graphs.
- **hist(x)**: Generates histograms of numeric data.
- **boxplot(x)**: Displays boxplots to visualize distribution.
- **barplot(height)**: Produces bar charts.
- **pairs(data)**: Creates scatterplot matrices to explore multivariate relationships.

Advanced Visualization with ggplot2

While not part of base R, the *ggplot2* package is widely used for creating complex, customizable visualizations using a grammar of graphics.

- **ggplot(data, aes())**: Initializes a ggplot object with data and aesthetic mappings.
- **geom_point()**: Adds scatterplot points.

- **geom_line()**: Adds line graphs.
- **geom_histogram()**: Creates histograms.
- **facet_wrap()**: Splits data into multiple plots based on factor variables.

Programming and Control Flow Functions

Efficient programming in R often requires control structures and custom function definitions. These functions and constructs help automate tasks and implement complex logic.

Conditional Statements

Conditional expressions control the flow of code execution based on logical tests.

- **if(condition) { }**: Executes code if the condition is TRUE.
- **else { }**: Executes code when the preceding *if* condition is FALSE.
- **ifelse(test, yes, no)**: Vectorized conditional function.

Loops and Iteration

Loops enable repetitive execution of code blocks, useful for tasks requiring iteration over elements.

- **for(variable in sequence) { }**: Executes code for each element in a sequence.
- **while(condition) { }**: Repeats code while the condition remains TRUE.
- **repeat { }**: Infinite loop until explicitly broken.
- **break**: Exits a loop prematurely.
- **next**: Skips the current iteration and continues the loop.

Function Definition

Creating reusable functions is fundamental to programming in R, allowing modular, maintainable code.

- **function_name <- function(args) { }**: Defines a new function with specified arguments.

- **return(value)**: Returns a value from the function.

File Input and Output Functions

Reading from and writing to external files is essential for data import/export in R. These functions support a variety of file formats and data sources.

Reading Data

R provides multiple functions to read data from text, CSV, and other file types.

- **read.csv(file)**: Reads CSV files into data frames.
- **read.table(file)**: Reads tabular data with customizable delimiters.
