Understanding the Basics of Regression Analysis

Before diving into the specifics of the Lee Kiyoung regressor, it's crucial to have a foundational understanding of regression analysis itself. Regression is a statistical method used to examine the relationship between one or more independent variables and a dependent variable.

Types of Regression

There are several types of regression techniques, including:

- **Linear Regression:** Models the relationship between two variables by fitting a linear equation.
- **Multiple Regression:** Extends linear regression by using multiple independent variables to predict a dependent variable.
- **Polynomial Regression:** Models the relationship as an nth degree polynomial, allowing for more complex relationships.
- **Logistic Regression:** Used for binary outcome variables, modeling the probability of a certain class or event.

Understanding these types will help you determine the best approach for your specific data analysis needs.

Using the Lee Kiyong Regressor

Once installed, you can start utilizing the Lee Kiyong regressor for your regression analysis. The manual provides detailed instructions on how to set up your data and run analyses effectively.

Data Preparation

Proper data preparation is crucial for successful regression analysis. Here are the key steps:

1. **Data Cleaning:** Remove any missing or erroneous data points. You can use Pandas to identify and fill or drop missing values.
2. **Feature Selection:** Choose relevant features that significantly impact the dependent variable. You can use correlation matrices or feature importance scores for this.
3. **Data Splitting:** Divide your dataset into training and testing sets, typically using a 70-30 or 80-20 split.

Running the Regression

To run a regression analysis using the Lee Kiyong regressor, follow these steps:

1. **Load Your Data:** Use Pandas to load your dataset:

```
```python
import pandas as pd
df = pd.read_csv('your_data.csv')
```
```

2. **Initialize the Regressor:**

```
```python
from lee_kiyong_regressor import Regressor
model = Regressor()
```
```

3. **Fit the Model:**

```
```python
model.fit(X_train, y_train)
```
```

4. **Make Predictions:**

```
```python
predictions = model.predict(X_test)
```
```

5. **Evaluate the Model:**

Use metrics such as Mean Absolute Error (MAE), Mean Squared Error (MSE), and R-squared to assess model performance:

```
```python
from sklearn.metrics import mean_squared_error, r2_score
mse = mean_squared_error(y_test, predictions)
r2 = r2_score(y_test, predictions)
```
```
