Preprocessing and Quality Control of RNA-seq Data

Proper preprocessing and quality control (QC) are crucial for reliable RNA-seq analysis results. Galaxy offers several tools to assess and improve raw sequencing data quality before downstream processing.

Quality Assessment Tools

Tools such as FastQC and MultiQC are integrated into Galaxy to evaluate raw RNA-seq data quality. These tools generate reports on sequence quality scores, GC content, adapter contamination, sequence duplication levels, and overrepresented sequences. Reviewing these reports ensures data integrity and identifies potential issues that could bias analysis.

Read Trimming and Filtering

Based on QC results, trimming tools like Trim Galore! or Cutadapt are used to remove adapter sequences, low-quality bases, and short reads. This step improves mapping accuracy and downstream quantification by eliminating artifacts and sequencing errors. Users can customize trimming parameters within Galaxy to suit their dataset characteristics.

Removing Contaminants and Ribosomal RNA

RNA-seq data often contain contaminating sequences such as ribosomal RNA (rRNA). Tools in Galaxy can filter out rRNA and other unwanted sequences to enhance the specificity of transcriptomic profiling. This filtering step enhances the sensitivity of gene expression measurements.

Alignment and Mapping Strategies

After preprocessing, the next step is to align RNA-seq reads to a reference genome or transcriptome. Galaxy provides multiple aligners optimized for RNA-seq data.

Choosing the Right Aligner

Popular RNA-seq aligners available in Galaxy include HISAT2, STAR, and TopHat2. Each tool offers distinct advantages: HISAT2 is fast and memory-efficient; STAR excels at detecting splice junctions; TopHat2 is flexible for novel splice site discovery. Selection depends on the experiment design and computational resources.

Alignment Workflow in Galaxy

Users can upload reference genome files and indexes or use pre-built references available in Galaxy. The alignment tool parameters, such as mismatch tolerance and reporting options, can be adjusted to optimize mapping quality. Galaxy records all settings, ensuring reproducibility.

Assessing Alignment Quality

Post-alignment, tools like SAMtools and Qualimap help evaluate mapping statistics, including alignment rates, coverage uniformity, and splice junction validation. These assessments inform whether data are suitable for downstream analysis.

Quantification and Normalization of Gene Expression

Quantifying transcript abundance accurately is essential to interpret RNA-seq data. Galaxy integrates tools for counting mapped reads and normalizing expression levels.

Counting Reads per Gene or Transcript

Tools such as featureCounts and HTSeq-count are used to assign aligned reads to genomic features like exons or genes. These tools generate count matrices that serve as input for differential expression analysis.

Normalization Methods

Normalization accounts for sequencing depth and other technical variations to make gene expression levels comparable across samples. Galaxy supports normalization methods like TPM (Transcripts Per Million), FPKM (Fragments Per Kilobase Million), and methods used by differential expression tools such as DESeq2 and edgeR, which apply more sophisticated normalization approaches.

Generating Expression Matrices

Galaxy workflows facilitate the generation of expression matrices from raw count data, enabling seamless integration with downstream statistical analysis tools. The platform supports various output formats compatible with visualization and functional annotation software.

Differential Expression Analysis

Identifying differentially expressed genes (DEGs) between experimental conditions is a primary goal of RNA-seq studies. Galaxy offers several statistical tools to perform this analysis efficiently.

Popular Differential Expression Tools in Galaxy

DESeq2, edgeR, and limma-voom are among the most widely used tools integrated into Galaxy for differential expression analysis. These tools model count data to identify genes with significant expression changes, considering biological variability and experimental design.

Setting Up the Analysis

Users input count matrices and specify experimental groups and contrasts. Galaxy's interface simplifies parameter selection, including filtering low-count genes and adjusting p-value thresholds. The platform also supports batch effect correction and complex experimental designs.

Interpreting Results

Differential expression results include fold changes, p-values, and adjusted p-values for multiple testing correction. Galaxy generates summary tables and visualizations such as MA plots and heatmaps to aid interpretation. These outputs assist researchers in prioritizing candidate genes for further validation.

Functional Annotation and Pathway Analysis

Beyond identifying DEGs, understanding their biological context is crucial. Galaxy provides tools for functional annotation and pathway enrichment analysis to interpret RNA-seq results.

Gene Ontology and Pathway Enrichment

Tools like GOrse and clusterProfiler integrated into Galaxy enable enrichment analysis based on Gene Ontology terms, KEGG pathways, and Reactome pathways. These analyses reveal biological processes, molecular functions, and cellular components associated with gene expression changes.

Visualization of Functional Data

Galaxy supports generating various plots such as bar charts, dot plots, and pathway maps to visualize enriched functions and pathways. These visualizations facilitate communication of findings and hypothesis generation.

Integrative Analysis

Researchers can combine differential expression results with other omics data or metadata within Galaxy to perform integrative analyses. This holistic approach enhances the understanding of complex biological systems.
